The alkali metals consist of the chemical elements lithium (Li), sodium (Na), potassium (K), rubidium (Rb), caesium (Cs), and francium (Fr). Together with hydrogen they constitute group 1, which lies in the s-block of the periodic table. All alkali metals have their outermost electron in an s-orbital: this shared electron configuration results in their having very similar characteristic properties.

1. Introduction. Small modular nuclear-fission reactors, known as SMRs, have been hailed as being transformative at many fronts. They are seen as the way to overcome the cost overruns and construction delays that plagued an industry dominated by large nuclear power reactors.

The double membrane that encloses the nucleus is known as the nuclear envelope; its purpose is to regulate molecules into and out of the nucleus and serve as a barrier to protect DNA integrity.
