It turns out, however, that the 100 trillion microbes living in and on people — that's ten single-cell organisms for every one human cell — are a fundamental component of human physiology. In a very real sense, the human microbiome is as much a functioning organ as are the intestines into which so many of them are packed.

It is not that it is impossible, you just have to remain organized when you do it. The major part of microbiology is going to be memorization of things, like names of structures and the like. With anatomy and physiology, you also have to do a lot of memorization as well, but the bulk of it is going to be remembering structure names and what they do.

The bacterial cell wall, to which the fibrils are attached, is also clearly seen as the light staining region between the fibrils and the dark staining cell interior. Incipient cell division is also indicated by the nascent septum formation (seen as an indentation of the cell wall) near the cell equator.
